# Android Architecture

Written in Java, executed in Dalvik VM. Home, Contacts, Phone, Browser, ...

Written mostly in Java. Managers for Activity, Window, Package, ...

Native libraries, daemons and services (C/C++). SQLite, OpenGL, SSL, ... Dalvik VM, Core libs

Drivers for hardware, networking, file system access, and inter-process-communication (IPC). Display, camera, flash, Wi-Fi, audio, ...

The Linux kernel, the libraries, and the runtime are encapsulated by the Application Framework. Developers typically work with the top two layers

# Android is NOT just “Java on Linux”

- ❑ Android uses Linux kernel. Only kernel
  - User land is totally different from usual Linux system
  
- ❑ Android apps are written in Java
  - Class libraries are similar to Java SE but not equal
  
- ❑ Dalvik VM eats only “dex” code
  - Need to translate from Java byte code in advance

# Linux Kernel – Standard Services

Provides generic operating system services

- ❑ Permissions architecture / Security – Restrict access to processes
- ❑ Memory and Process Management
- ❑ Low-level details – File and Network I/O
- ❑ Device Drivers – memory, radio, camera, ...

<http://www.androidcentral.com/android-z-what-kernel>

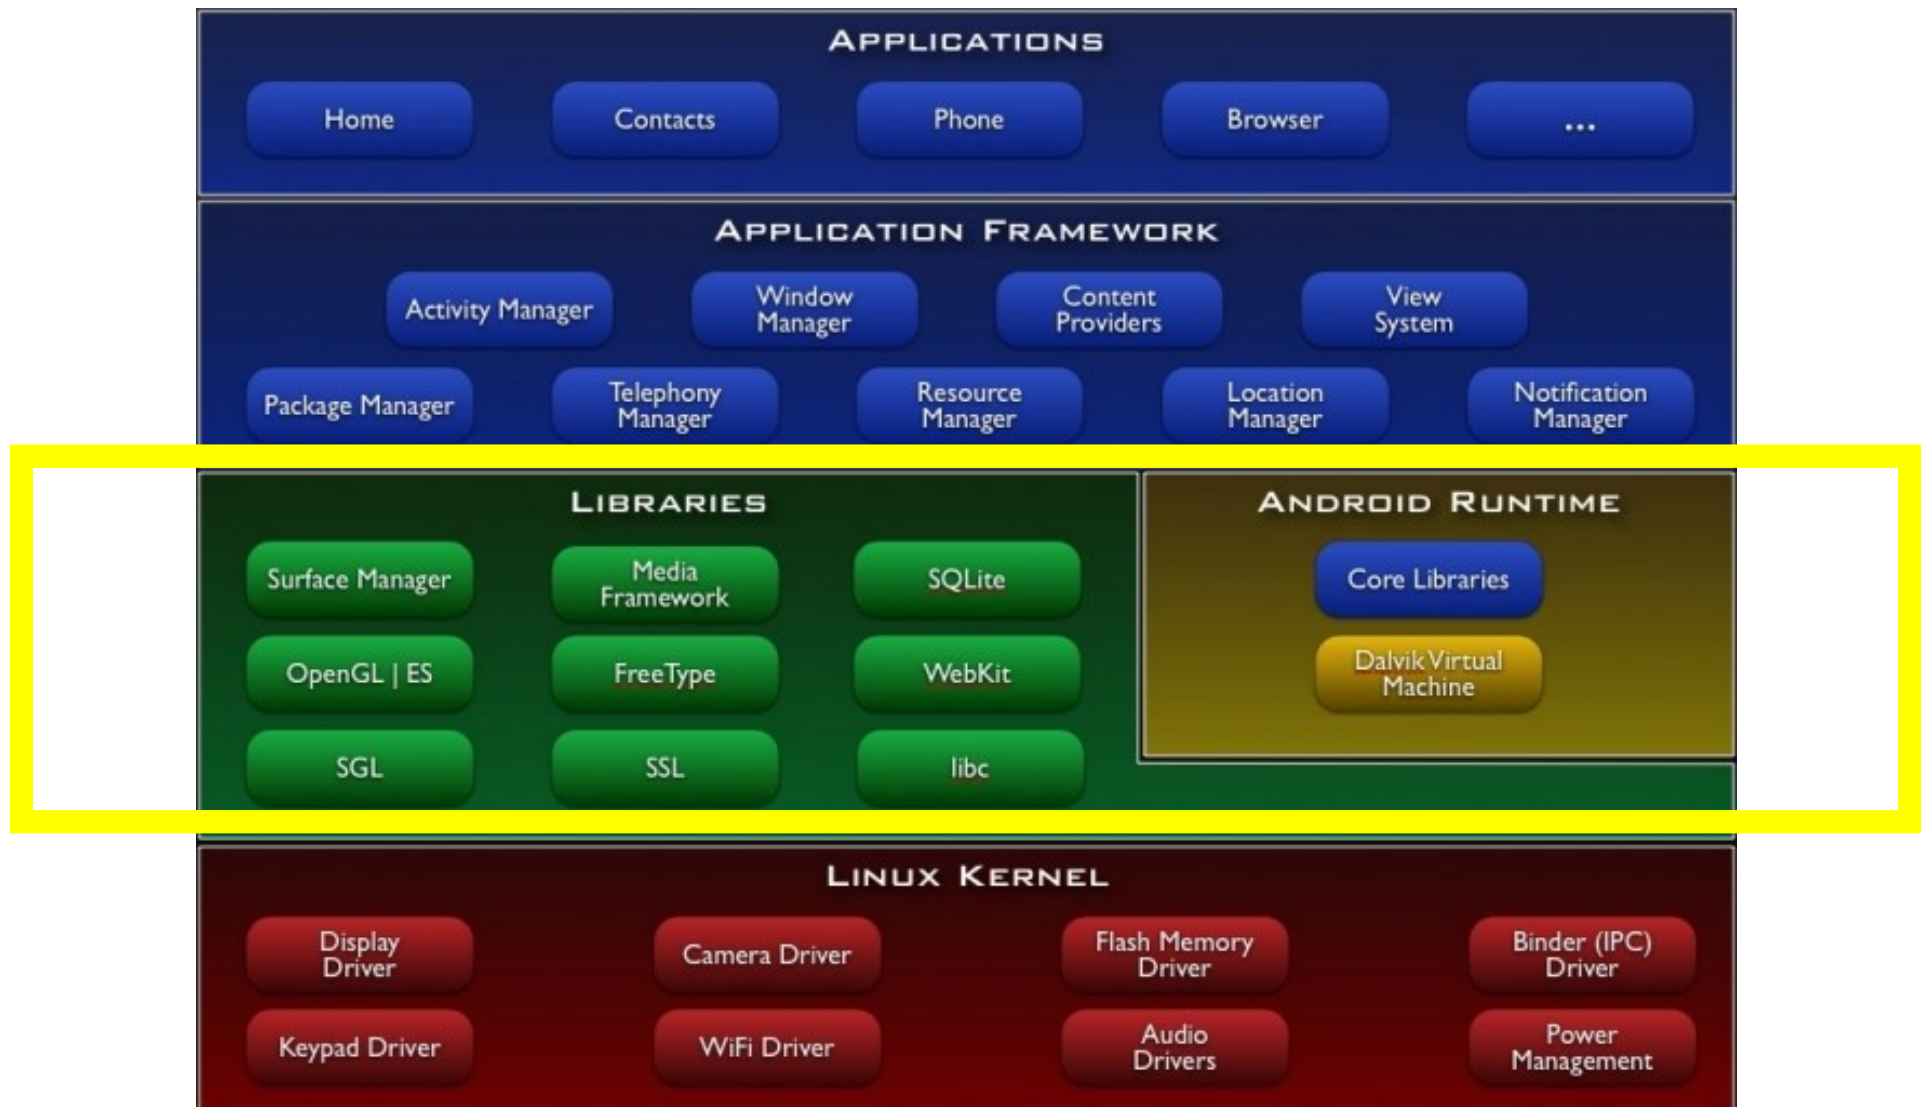

# Linux Kernel – Android Specific Services

For better management of mobile devices

About 249  
patches, 25000  
lines of code

- ❑ Power management – wakelock for early suspend
- ❑ Android shared memory
  - ashmem (virtual), pmem – process memory allocator (contiguous)
- ❑ Low memory killer – as opposed to Out-Of-Memory killer
- ❑ Inter-process communication (IPC) – binder
- ❑ System logging facility – logger
- ❑ Increase security – paranoid network security

# Native Libraries (C/C++)

# Native Libraries (C/C++)

Handle core performance-sensitive activities (e.g., quickly rendering webpages, updating display)

- ❑ System C Library – (Bionic libc) process/thread creation, computation, memory allocation, ...
- ❑ Surface Manager – display management
- ❑ Media Framework – playing audio/video files
- ❑ Webkit - rendering / displaying webpages
- ❑ OpenGL – high performance graphics
- ❑ SQLite – managing in-memory relational databases

# Android Runtime

- ❑ Core Java Libraries
- ❑ Dalvik Virtual Machine (Dan Bornstein from Google)

# Core Java Libraries

To make it easier to write Java apps, Android provides many reusable Java building blocks / packages

- ❑ Basic Java classes – java.\* javax.\* (basic data structure, file I/O, concurrency mechanisms)
- ❑ App lifecycle – android.\*
- ❑ Internet / Web services – org.\*
- ❑ Unit Testing – junit.\*

# Dalvik Virtual Machine

It is the software that executes Android apps (not the Java VM), specifically designed to run on

- Slow CPU
- Relatively little RAM
- OS without swap space
- Powered by a battery
- Diverse set of devices
- Sandboxed application runtime for security, performance, and reliability

Somewhat conflicting  
constraints

# Dalvik Virtual Machine

## Google's Approach to Implement Dalvik VM

- ❑ Every Android app runs in its own process with its own instance of Dalvik VM
- ❑ Supports a device running multiple VMs efficiently
- ❑ Dalvik executable (.dex) format optimized for minimal memory
- ❑ Transforms .class files into .dex by “DX” tool
- ❑ Register-based VM
- ❑ Relies on Linux kernel for threading and low-level memory mgmt

# Dalvik Virtual Machine

## Memory Efficiency

- ❑ Total system RAM: 64 MB (can be 100 MB for newer phones)
  - Available RAM after low-level startup: 40 MB
  - Available RAM after high-level services have started: 20 MB
  
- ❑ Multiple independent mutually-suspicious processes
  - Security model: separate address spaces, separate memory
  
- ❑ Large (rich) system library: 10 MB

# Dalvik Virtual Machine

## Typical Workflow

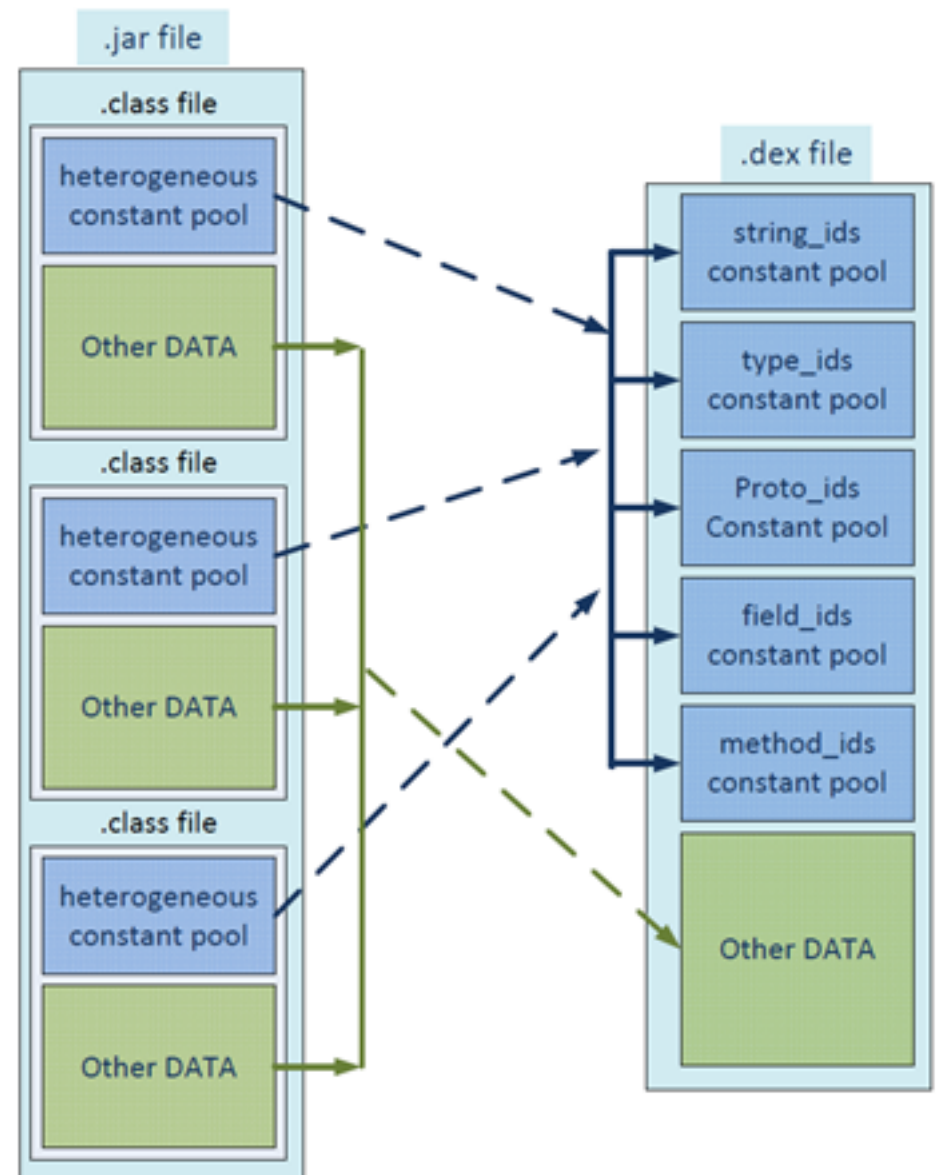

- ❑ Write apps in Java
- ❑ Compile into Java bytecode
  - One .class file per class
- ❑ DX tool converts multiple Java classes into a single DEX file (classes.dex)
  - Rearranges classes, removes redundancy
- ❑ Dex file is packaged with other resources and installed on device

# Dalvik Virtual Machine

## Conserving Memory

- ❑ .dex uses shared, type-specific constant pools
  - Minimal repetition and more logical pointers than a .class file
- ❑ A constant pool stores all literal constant values within the class
  - String constant, field, variable, class, interface, and method names
- ❑ In a .class file, constant part: 60%, method part: 33%

# Dalvik Virtual Machine

.dex cuts the size in half of some common system lib and apps

<b>Code</b>	<b>Uncompressed JAR (bytes)</b>	<b>Compressed JAR (bytes)</b>	<b>Uncompressed DEX (bytes)</b>
Common System Libraries	21,445,320 (100%)	10,662,048 (50%)	10,311,972 (48%)
Web Browser App	470,312 (100%)	232,065 (49%)	209,248 (44%)
Alarm Clock App	119,200 (100%)	61,658 (52%)	53,020 (44%)

- ❑ Memory sharing optimizations do not come for free
  - Redesigned garbage collector to keep “mark bits,” indicating that an object is reachable, and therefore, should not be garbage collected

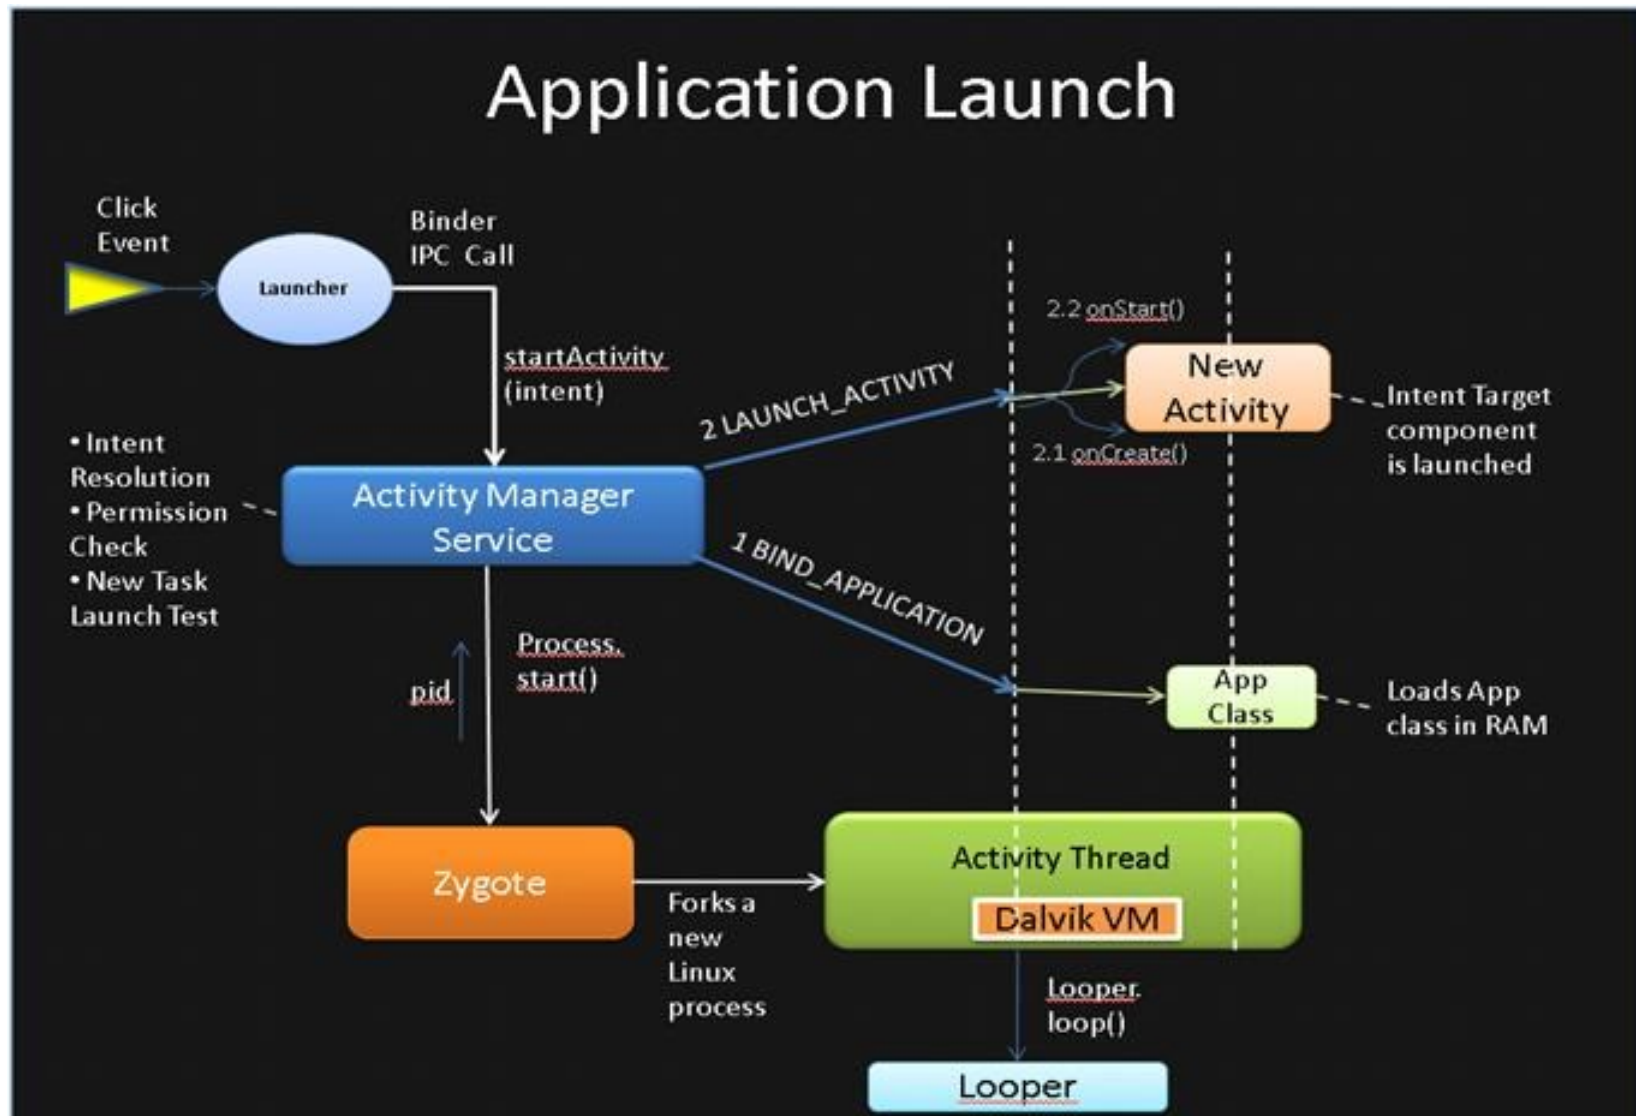

# Dalvik Virtual Machine

The Zygote – Initial cell / earliest dev. stage of an embryo

- ❑ Enables sharing of code across VM instances and provides fast startup time for new VM instances
- ❑ A VM process that starts at system boot time
  - Initializes Dalvik, which preloads and pre-initializes core library classes (most are read-only)
  - When written, use “copy-on-write” behavior
- ❑ Waits for socket requests from runtime processes to fork new VM instances
- ❑ In Java VM, each VM instance has an entire copy of the core library class and associated heap objects – memory not shared across instances

# Dalvik Virtual Machine

# Dalvik Virtual Machine

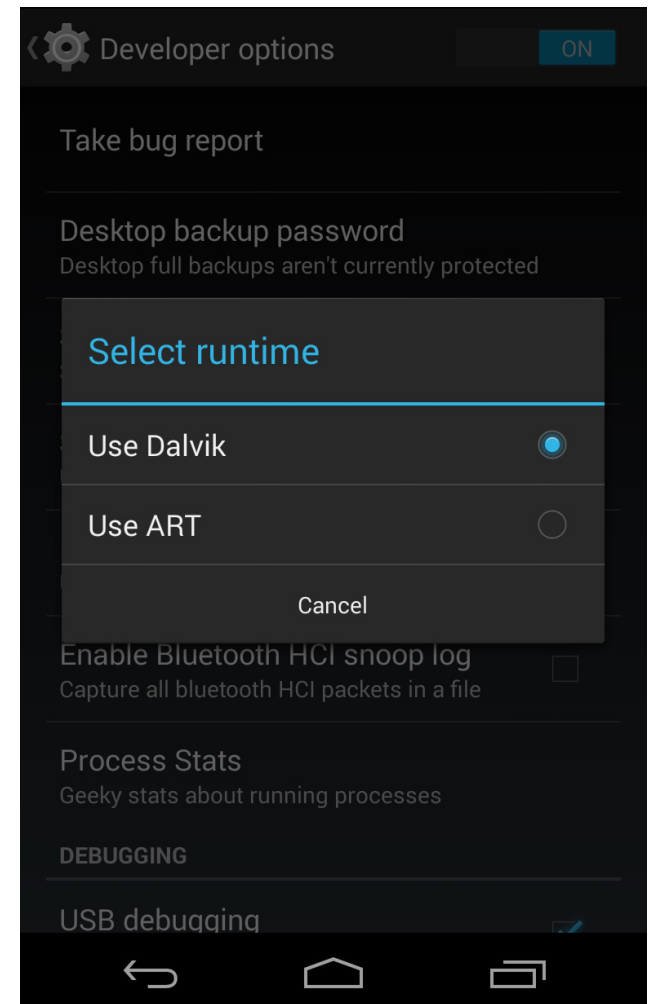

## Register-Based Architecture

- ❑ Traditional VMs are stack-based
  - Simplicity of implementation, ease of writing compiler backend
  - But cost of performance
- ❑ Registered-based architectures require
  - 47% less executed VM instructions than stack-based
  - 25% larger registry code, but only 1.07% extra real machine loads per VM instruction
  - Overall, 32.3% less time to execute, on average
- ❑ Appropriate for resource-constrained devices
  - 25% more code, but 50% reduction in code-size through shared constant pools in .dex file

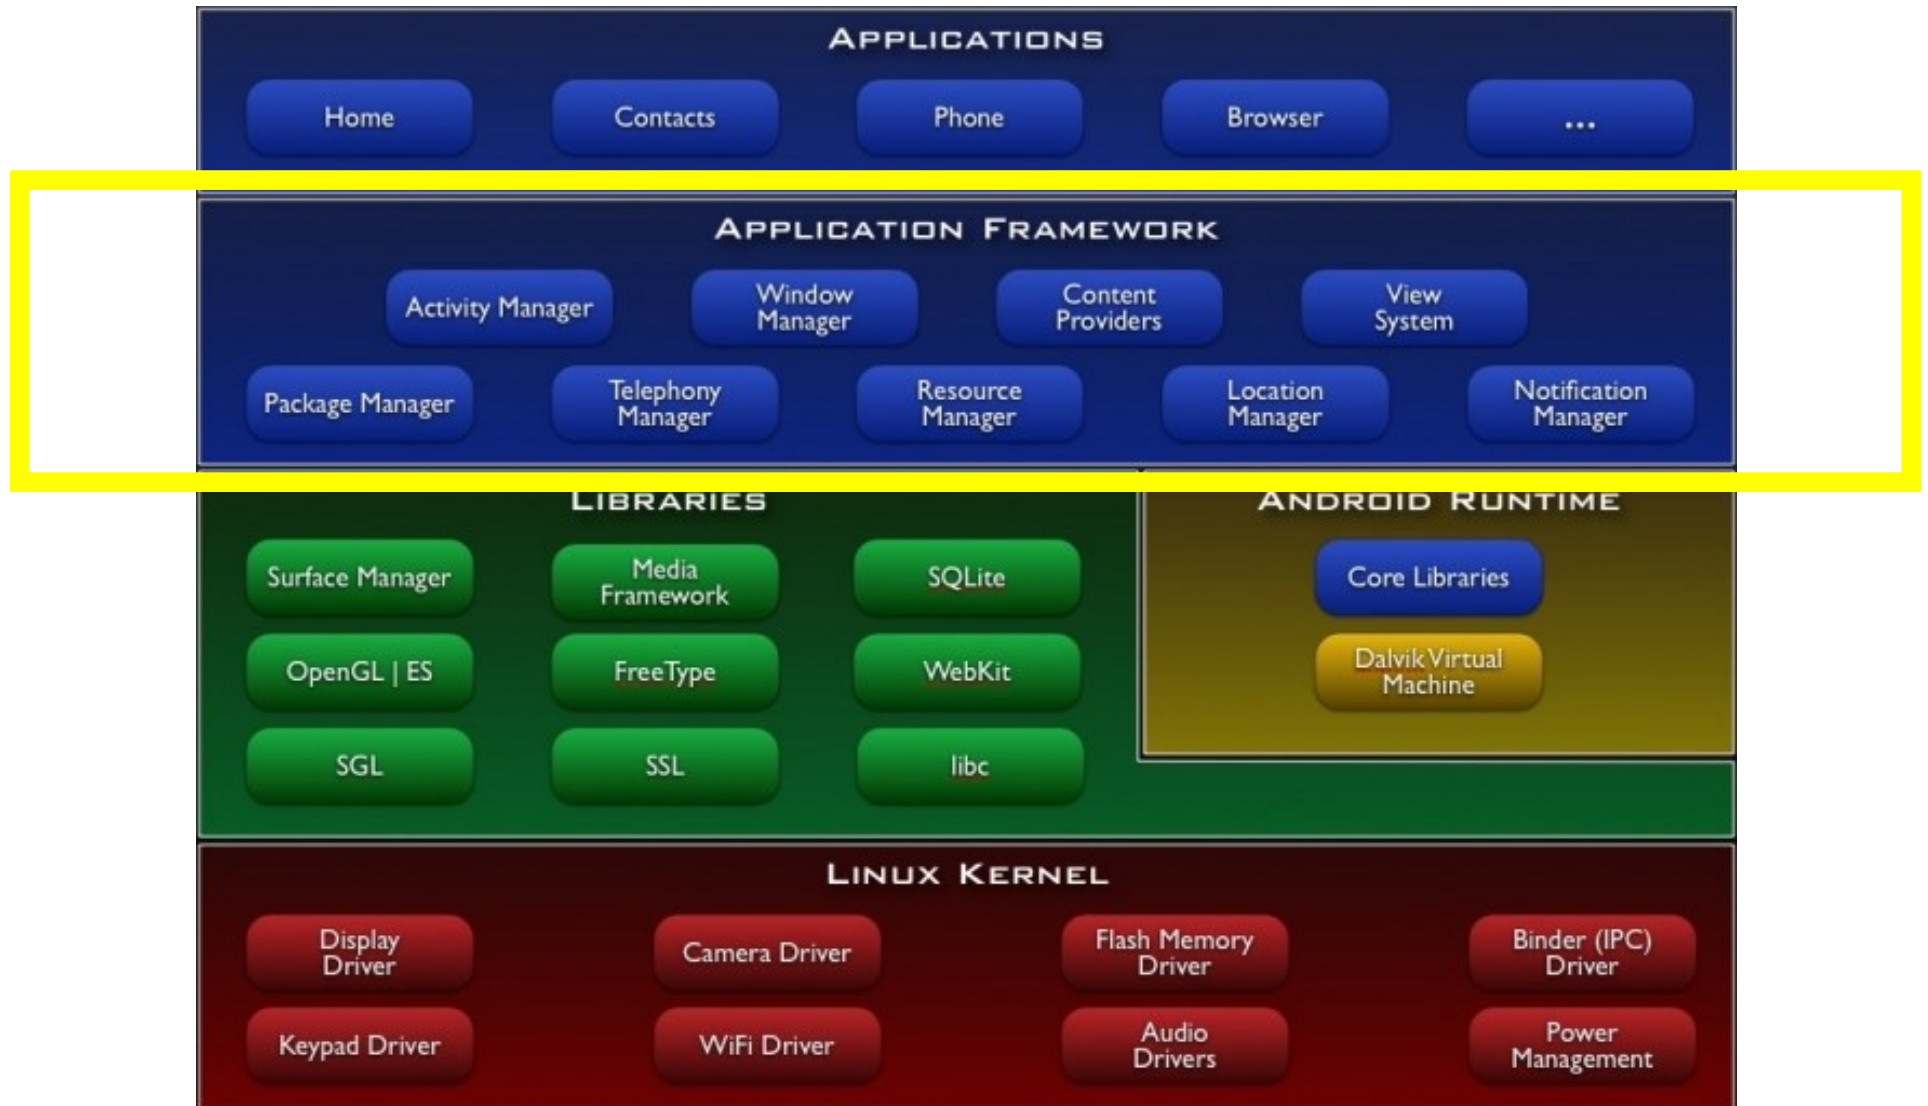

# Android ART

Android Run Time : Google finally moves to replace Dalvik, to boost performance and battery life. Early version included in Android KitKat

- ❑ ART straddles a middle-ground between compiled and interpreted code, called “ahead-of-time” (AOT) compilation
- ❑ Currently apps are interpreted at runtime using JIT (slow), compare with iOS
- ❑ With ART, app is compiled into native code while installing (fast)

# Application Framework

# Application Framework

A collection of reusable software components that many mobile apps will need

- ❑ Package Manager – a database tracking all apps installed
  - Allows one app to find/contact another and share data
- ❑ Window Manager
  - Manages the windows comprising the app
- ❑ View System – provides common UI elements
  - tabs, icons, text entry boxes, buttons
- ❑ Resource Manager – manages non-compiled resources
  - strings, graphics, layout files (choice of languages)

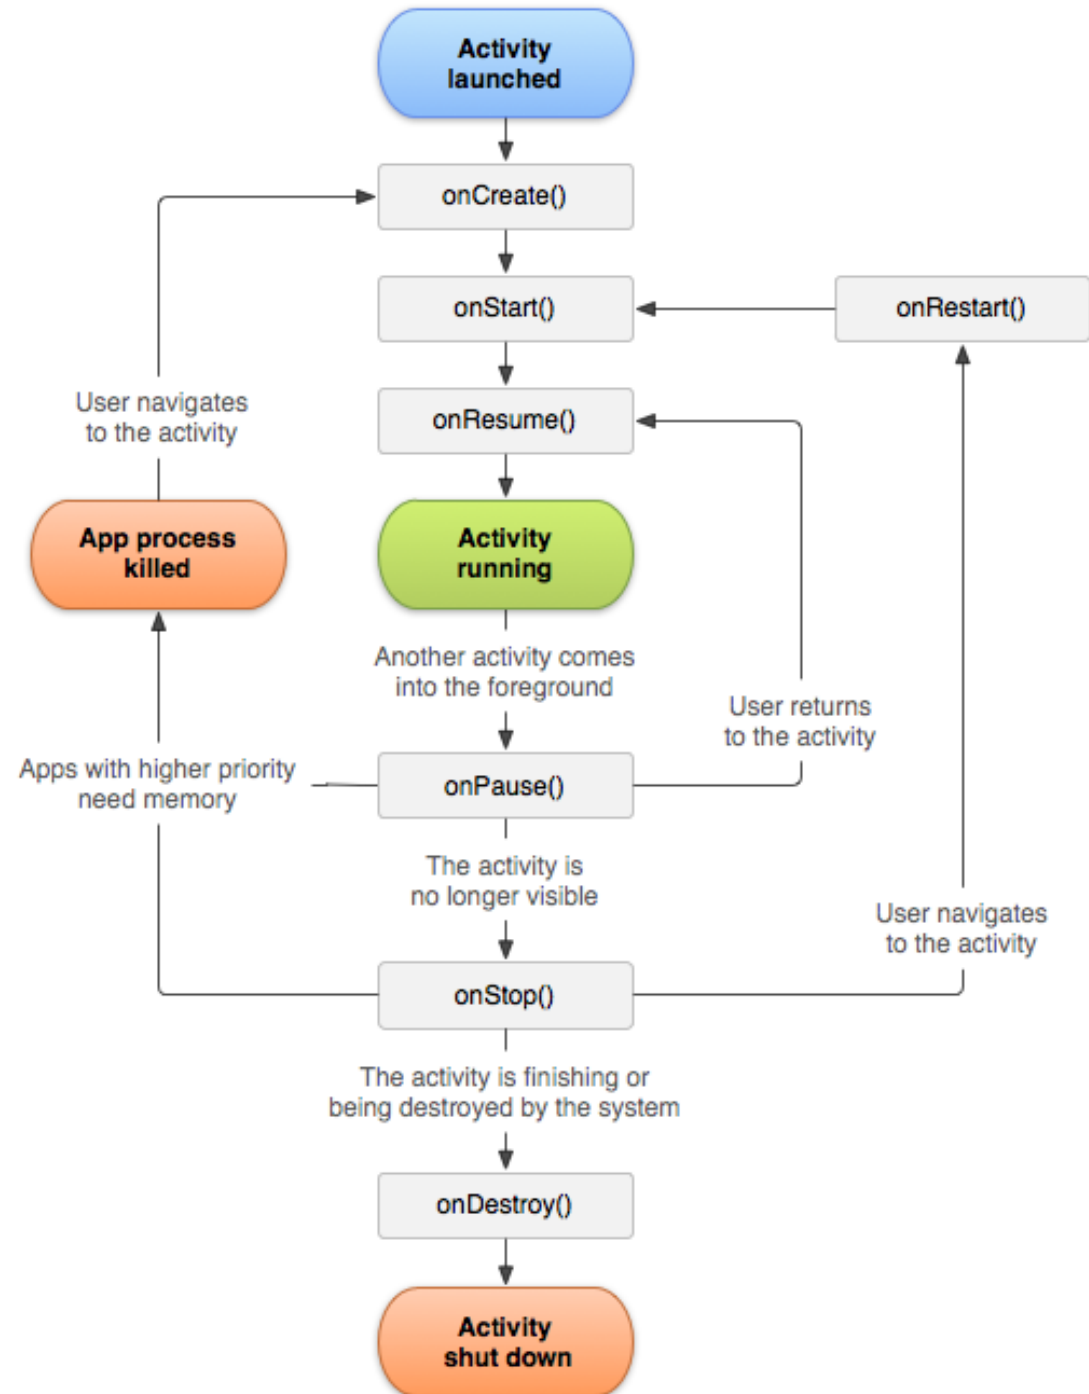

# Application Framework

- ❑ Activity Manager – coordinates and supports navigation across multiple UI screens
  - Playing music
- ❑ Content Provider – databases allowing multiple apps to store and share structured information
  - Phone app accesses Contacts app to dial phone numbers
- ❑ Location Manager – allows apps to receive location and movement information
  - GPS to do context-specific tasks, e.g., finding directions
- ❑ Notification Manager – place notification information in the status bar when important events occur
  - MMS received while emailing / calling

# App Lifecycle

Lifecycle is a set of states

- ❑ When the current state changes, Android OS notifies the Activity of that change
- ❑ Implemented by callback methods

# App Lifecycle

## Four States

- Active / Running
  - Visible, has focus, and in foreground
- Paused
  - Partially visible but not active and lost focus
  - Completely alive and maintains its state
- Stopped
  - Completely obscured by another activity
- Destroyed / Dead
  - No longer in memory

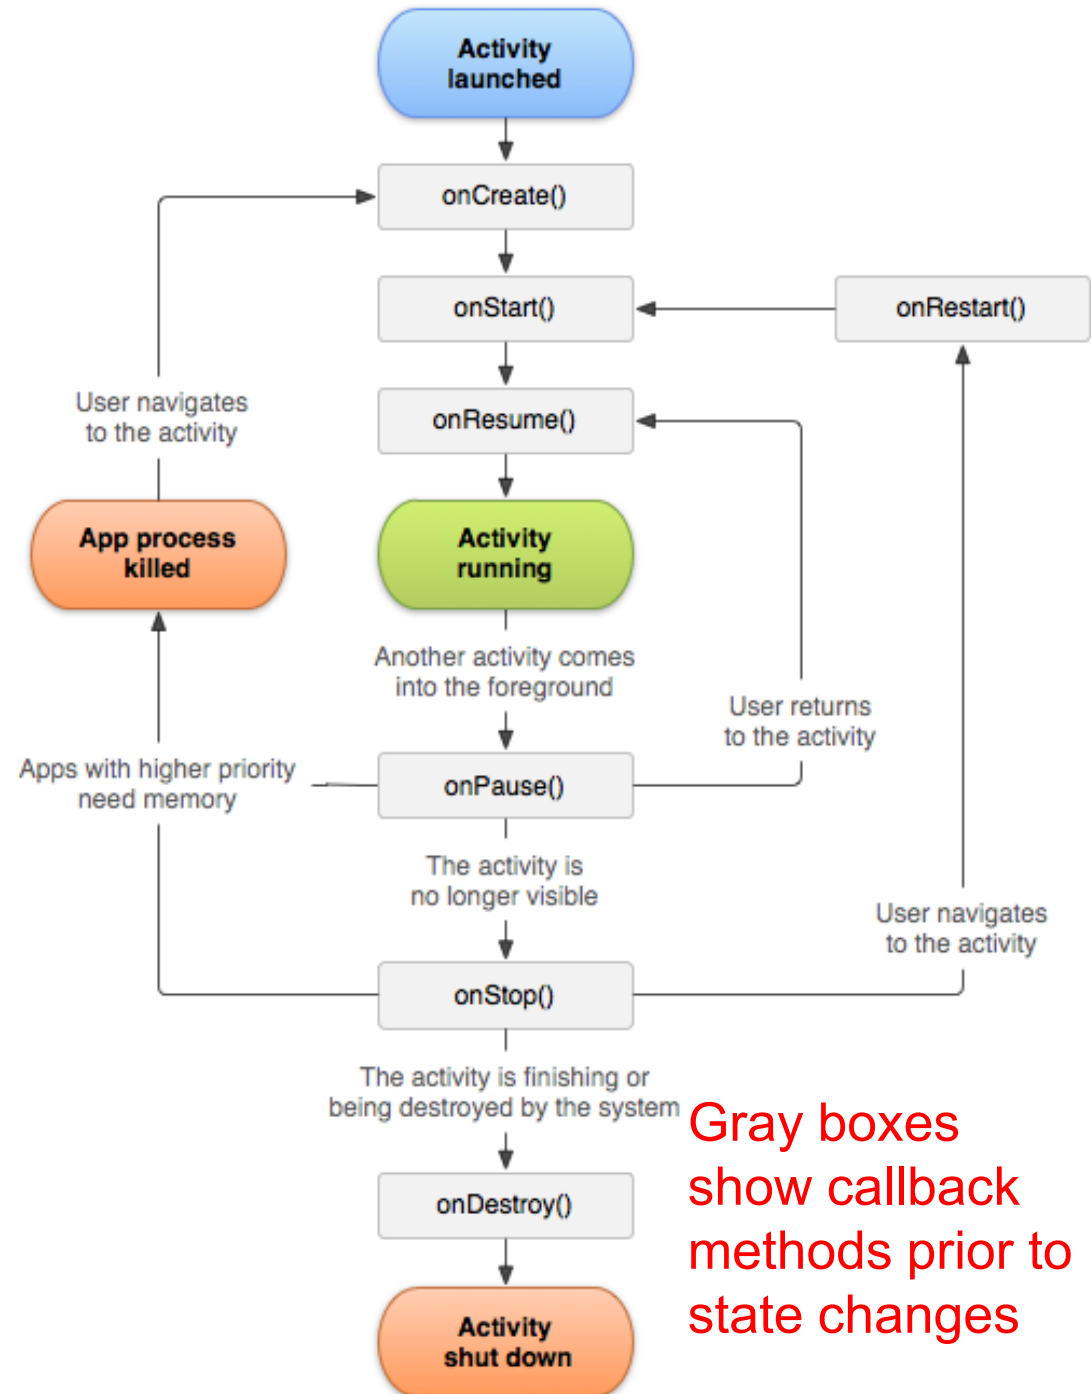

# App Lifecycle

## Seven Callback Methods

- ❑ onCreate() – UI creation and initialization of data elements
- ❑ onStart() – called before Activity is visible (but not alive)
- ❑ onResume() – Activity becomes visible and active for user to interact
- ❑ onPause() – another Activity comes in front, or user navigates away

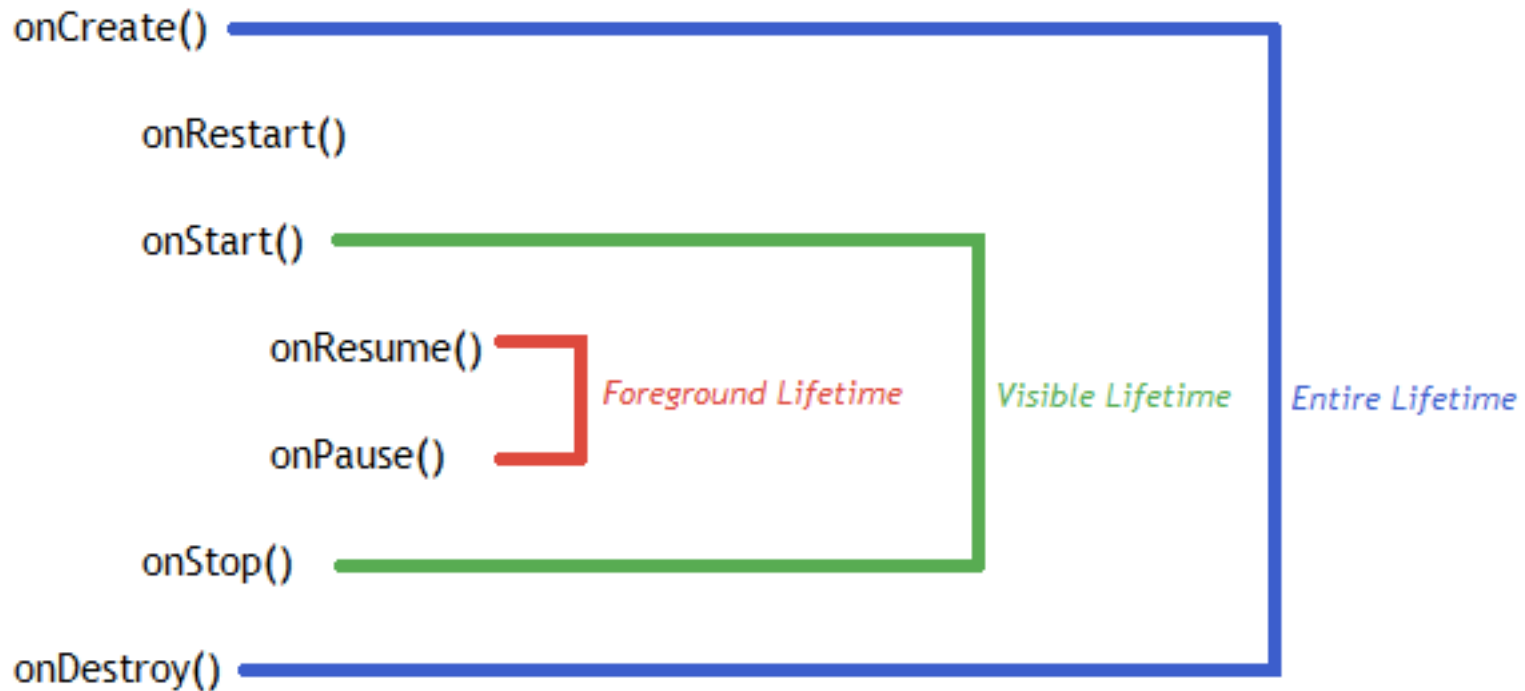

# App Lifecycle

## Seven Callback Methods

- ❑ `onStop()` – back button, or new Activity completely covers
- ❑ `onRestart()` – user navigates back to the Activity
- ❑ `onDestroy()` – Activity is destroyed

# App Lifecycle

# App Lifecycle

Three Lifecycle loops for every Activity, defined by callback methods

- ❑ Entire Lifetime – first call to onCreate() and final call to onDestroy()
- ❑ Visible Lifetime – from onStart() and onStop()
- ❑ Foreground Lifetime – from onResume() to onPause

# App Lifecycle

## Saving Persistent State

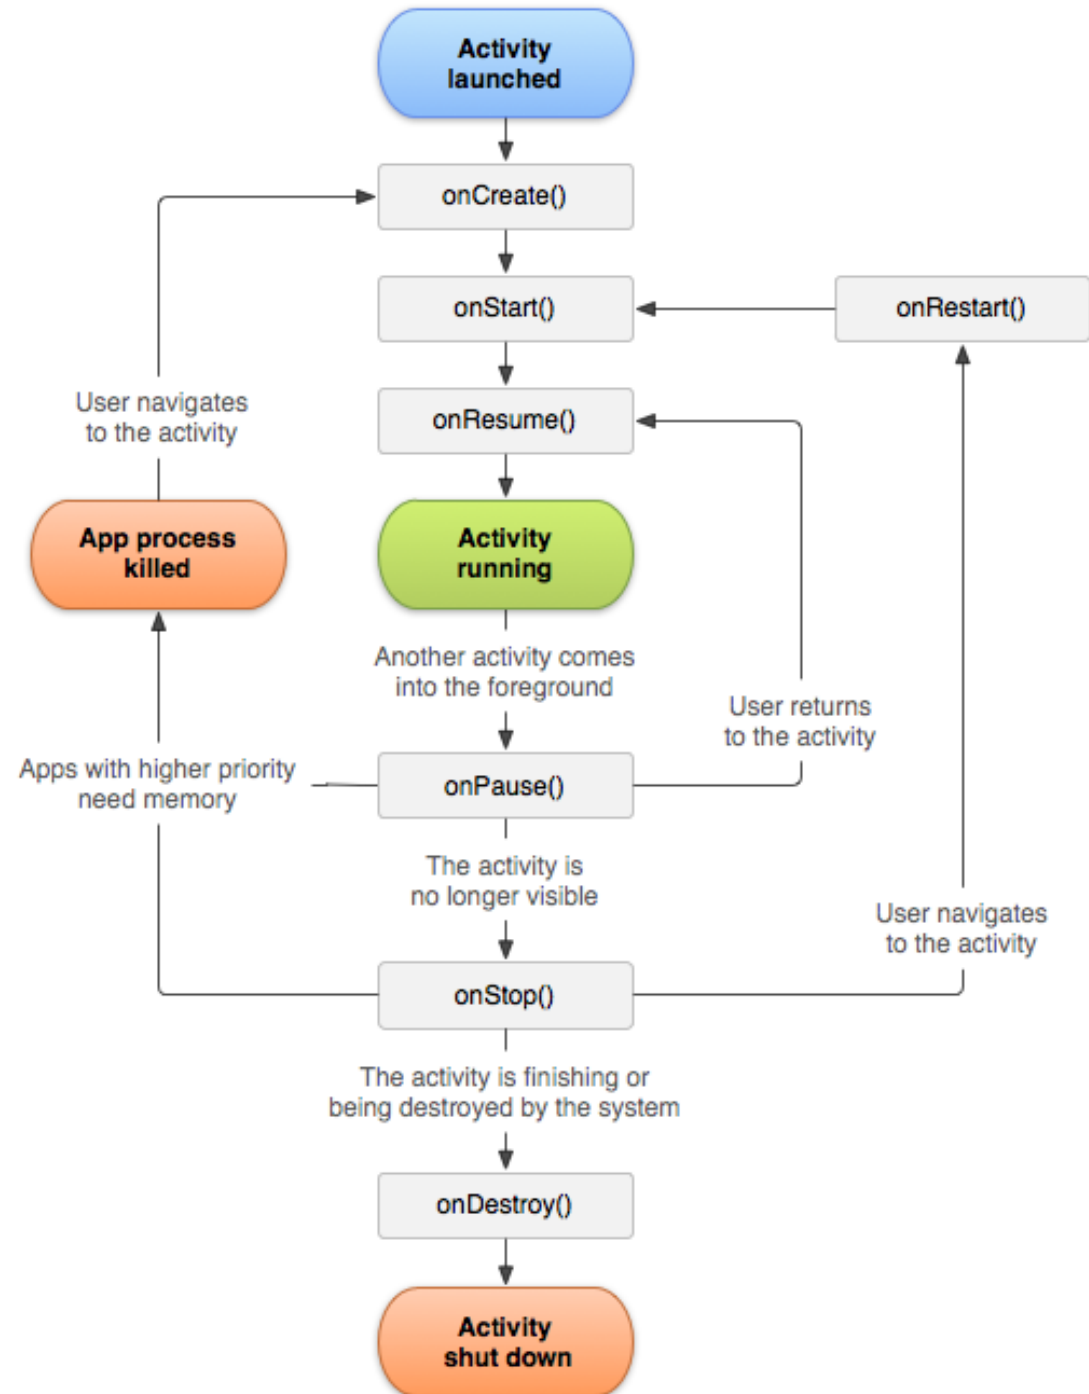

- ❑ When an Activity is stopped or paused, its state is preserved
- ❑ When an Activity is destroyed by the system, it is recreated next time Activity starts
- ❑ User is often unaware that an Activity is destroyed, resulting in surprises and crashes

# App Lifecycle

## Two Kinds of Persistent States

- ❑ Shared document-like data
  - SQLite storage using a content provider
  - “Edit-in-Place” user model
  - Backup fully at onPause()
- ❑ Internal state (user prefs)
  - API calls to store prefs
  - E.g., user’s initial calendar display (day vs week view), or default webpage in a browser

# Applications

- ❑ Standard apps include
  - Home – main screen
  - Contacts – contacts database
  - Phone – dial phone numbers
  - Browser – view web pages
  - Email Reader – compose and read email messages
  
- ❑ Nothing special about these apps
  - You can substitute your own or 3<sup>rd</sup> party app for any of them

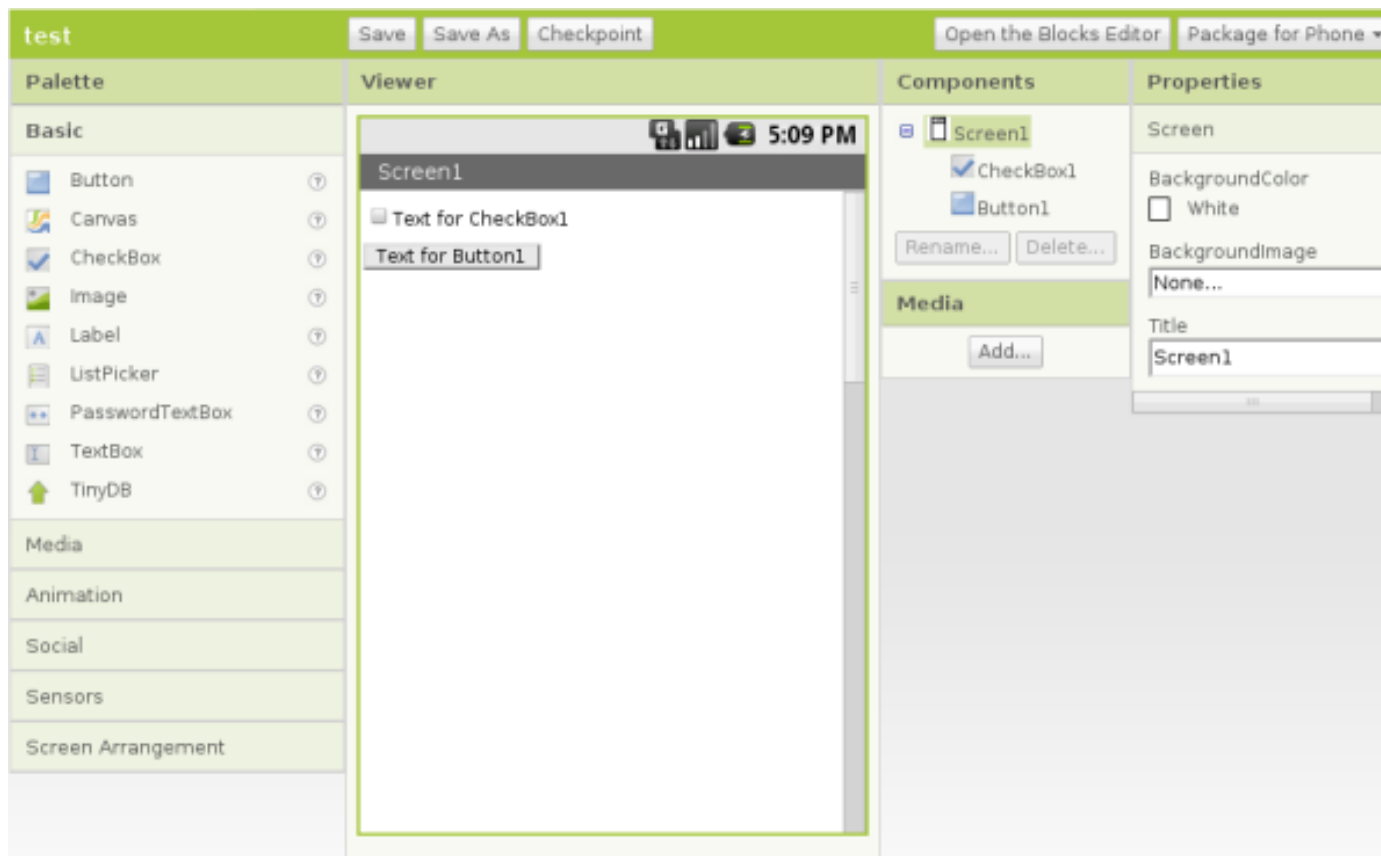

# Android App Inventor

- ❑ A produce of Google Labs

<http://appinventor.mit.edu/explore/>

- ❑ A web based graphical cloud-based tool for rapid development

# Android Development Environment

- ❑ Eclipse IDE
- ❑ Android Emulator
- ❑ Eclipse debugger
- ❑ Other tools
  
- ❑ Prerequisites
  - JDK6 installed (its not the latest version of Java)

# Android Emulator

## ❑ Pros

- Hardware is reconfigurable (memory, display size)
- Changes are non-destructive

## ❑ Cons

- Some features unavailable (no Bluetooth or USB connections)
- Performance / user experience can be misleading

# Fun with Math

$$S = 1 + 2 + 3 + 4 + \dots ?$$

- a) Infinity
- b) Does not converge (diverges)
- c) A finite value
- d) A Googolplex  $10^{(10)^{100}}$
- e) Confused

$$S = -1/12 \quad \text{Is it Absurd?}$$

# Fun with Math

Okay, let's define two more series:

$$S_1 = 1 - 1 + 1 - 1 + \dots ?$$

The sum depends on where we stop the series

1. 1, if we stop at odd location
2. 0, if we stop at even location

So,

$$S_1 = \frac{1}{2}$$

# Fun with Math

Okay, let's define two more series:

$$S_2 = 1 - 2 + 3 - 4 + \dots ?$$

Now add  $S_2$  to itself, but by shifting. So

$$\begin{aligned} 2S_2 &= 1 - 2 + 3 - 4 + \dots \\ &\quad 1 - 2 + 3 - 4 + \dots \\ &= 1 - 1 + 1 - 1 + 1 - \dots \\ &= S_1 = \frac{1}{2} \end{aligned}$$

Therefore,  
 $S_2 = 1/4$

# Fun with Math

Now, subtract  $S_2$  from  $S$  (the original sum)

$$S = 1 + 2 + 3 + 4 + \dots$$

(minus)

$$S_2 = 1 - 2 + 3 - 4 + \dots$$

$$S - S_2 = 0 + 4 + 0 + 8 + 0 + 12 + \dots$$

$$= 4(1 + 2 + 3 + \dots)$$

$$= 4S$$

$$3S = -S_2$$

$$= -1/4$$

$$\Rightarrow S = -1/12$$

Analytic continuation  
of the Riemann-Zeta  
function

$$\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s}$$
